### USING SYMMETRY TO FIND $f^{-1}(x)$

From our discussion of functions and their inverses, we have come to the conclusion that to find the inverse of  $f(x)$ , simply exchange the roles of  $x$  and  $y$ . For example,  $(1,4)$  becomes  $(4,1)$  and  $y = 3x + 5$  becomes  $x = 3y + 5$ . Graphically, this presents some interesting results.

$$\text{Let } f(x) = \{(1,-2), (3,4), (-1,-7)\}$$

$$\text{Thus } f^{-1}(x) = \{(-2,1), (4,3), (-7,-1)\}$$

Let's look at their corresponding graphs.

Notice that the midpoint of each point and its inverse point lies on the line  $y = x$ .

$$(1,-2) \text{ and } (-2,1) \quad \text{have a midpoint of} \quad (-1,-1)$$

$$(3,4) \text{ and } (4,3) \quad \text{have a midpoint of} \quad (3\frac{1}{2}, 3\frac{1}{2})$$

$$(-1,-7) \text{ and } (-7,-1) \quad \text{have a midpoint of} \quad (-4,-4)$$

Thus, a point and its inverse are symmetric to the line  $y = x$ . We can use this observation to help us graph the inverse of a function.

Consider the following function.

For each point on this graph, we can find its inverse point by plotting a point symmetric to it across the line  $y = x$ .

And, the result is the graph of the inverse function.
